Mastering the layering system Despite the growing popularity of photo-editing programs like Photoshop, the fundamental concept of manipulating digital images still comes from the original method of manipulating a negative. In this method, multiple photographs are used to make a single printing plate to produce prints. At one time, only pictures taken with chemical film could be retouched like this, with an operator painstakingly moving the photos on a grid board to create the printed image. Thankfully, that approach is a thing of the past as digital imaging and computer technologies developed over the last few decades. Today, two things are common to the layering process: * Layers are the foundation of Photoshop editing. Whether you use layers, channels, or some hybrid of the two, you can change the opacity and color of any image with layers. * Every layer has an object; other objects are _obtained_ by using a blend mode. Each layer has its own object and properties. You can switch between layers by simply changing the layer's order on the Layers panel.

Project Summary The HIV epidemic continues unabated, with 1.2 million new infections occurring worldwide in 2011, despite widespread access to combination antiretroviral therapy (cART). A significant proportion of HIV-infected individuals develop chronic non-AIDS diseases and co-morbidities, and while combination antiretroviral therapy has greatly extended life expectancy in this population, it is now recognized that there is a growing burden of HIV-related illnesses, including cardiovascular, metabolic, hepatic, renal, and malignancies. Patients on cART experience greater incidence and accelerated progression to AIDS and non-AIDS diseases than the general population, which is thought to be due to ongoing inflammation and immune activation. However, while these observations suggest that virologic control can directly impact the natural history of HIV disease, the mechanisms linking viral replication to this greater disease burden remain incompletely understood. It is known that elevated levels of inflammation and immune activation are present in individuals with uncontrolled viral replication, and that proinflammatory cytokines such as tumor necrosis factor (TNF) and interleukin-6 (IL-6) are associated with adverse outcomes in both HIV-infected and uninfected individuals. In addition, increased concentrations of pro-inflammatory cytokines such as TNF, IL-6 and sCD14 (a marker of systemic inflammation) have been linked to the development of cardiovascular disease, insulin resistance, and hepatic dysfunction in the general population. In HIV-infected individuals, chronic inflammation and immune activation, as well as levels of pro-inflammatory cytokines, are higher in virologic controllers than in individuals with plasma HIV RNA levels
